

The pain from Jonna's fractured arm is distracting and renders her unreliable for the focused spine assessment. It might also be argued that because she did not lose consciousness, that a mechanism for an unstable spine injury is not present or very low. In either case, you need to get to the ground. Splint Jonna's arm and lower her off the climb; if possible, leave her fingers free to help her set anchors on the way down, at least to protect herself when you are on rappel. Her knee injury is stable and cleaning of the abrasions can wait until you are safely on the ground. Jonna appears to have a mild concussion; continue to monitor her, especially during your descent. With no loss of consciousness, she will not develop increased ICP but will require both mental and physical rest to completely heal. After cleaning and dressing her abrasions, begin a Level 3 Evacuation: Her arm needs attention and she may require imaging to rule out a spine injury. Since she is ambulatory, she can walk out; although, she may need assistance navigating rough terrain.
